Search

Finding a document by what it says, not by what it is called.

Searching · every document

Searching in every document

Scope, not file names

Every markdown file in the space, by what it says.

Box and results, in one column

One column, one conversation

The box and what it found are next to each other, in the column you navigate from.

Text, not file names

The index is a cache

Delete it and reopening the space rebuilds it from the files on disk.

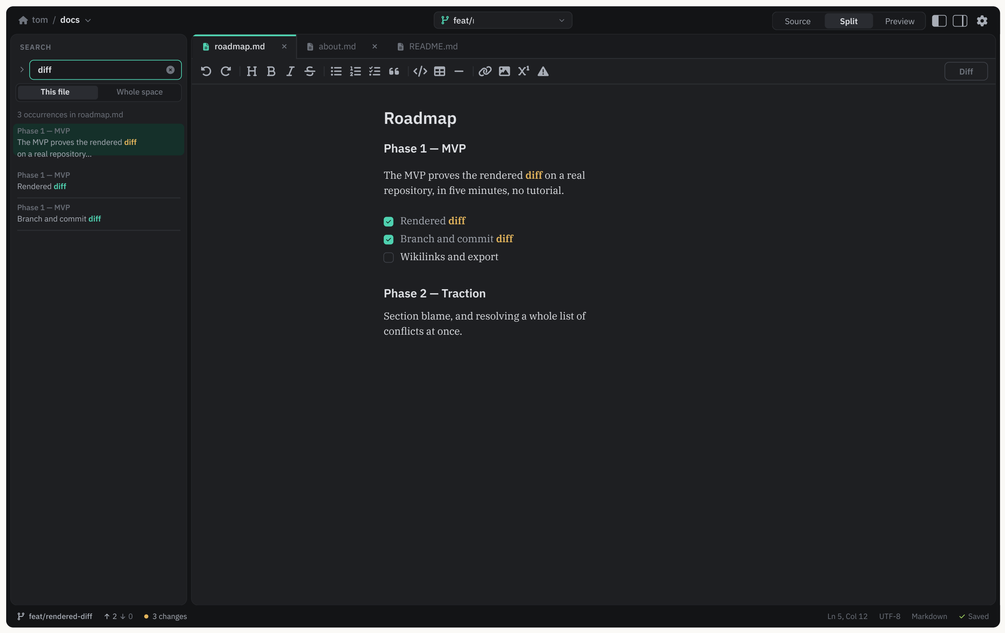

What is typed is words

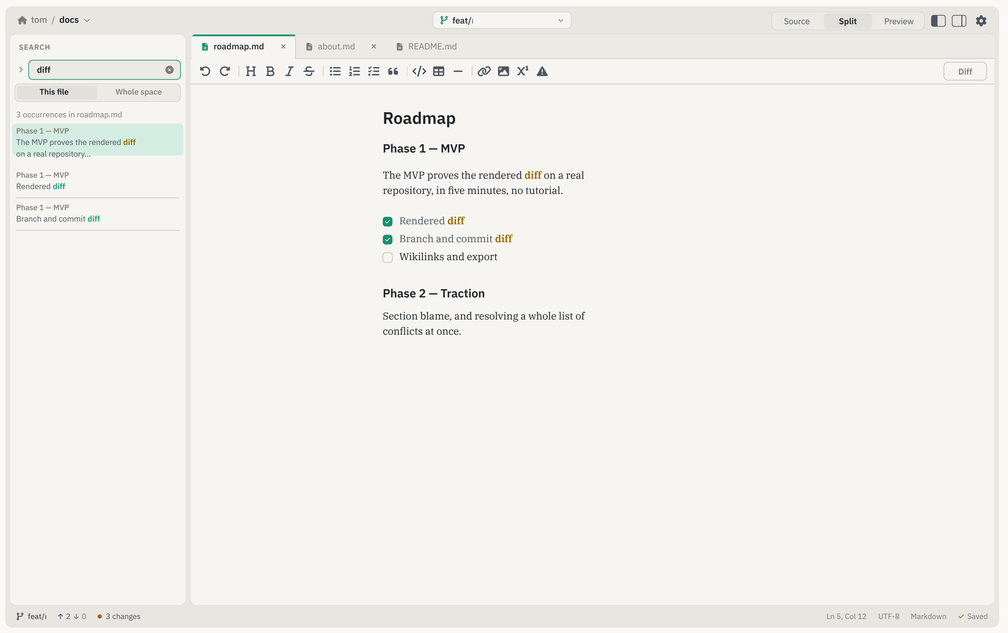

In any order, the last possibly half-typed. Never a query language, and no character a keyboard has means anything but a word or a break between two.

The scope is always visible

`This file · Whole space` sits under the box and is never revealed by focus. Which one is chosen is said by the control, not guessed from what came back.

Searching · the open file

Searching in the open file

The same box, a different reach

Scope decides whether the answer is a list of documents or a list of occurrences.

Every occurrence, in order

The line it is on and the words around it, so you know which one it is before you go.

It where it is

The matches stay marked in the document, with the selected one stronger than the rest.

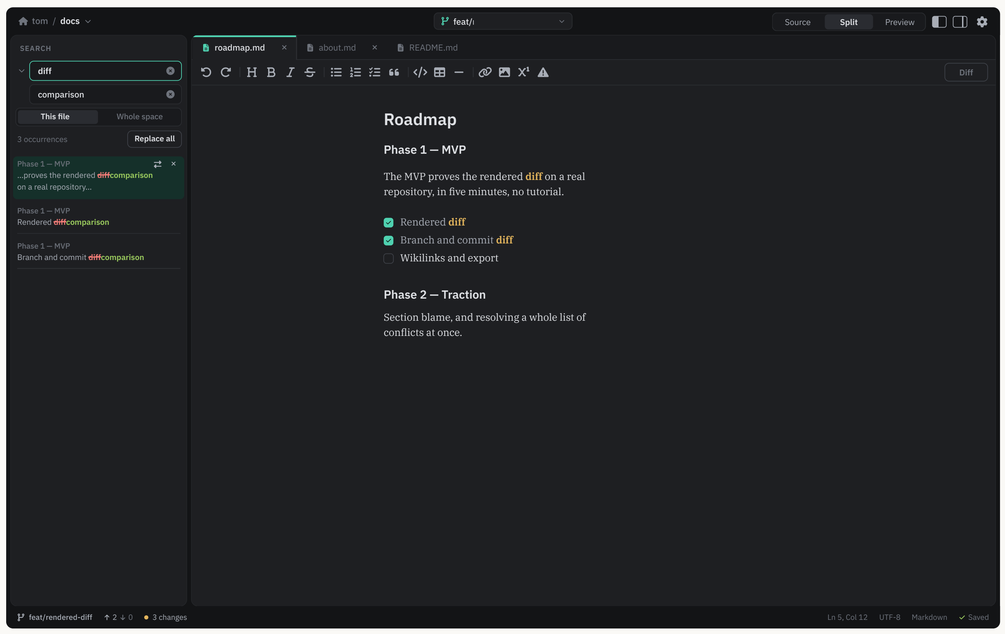

One of them is current

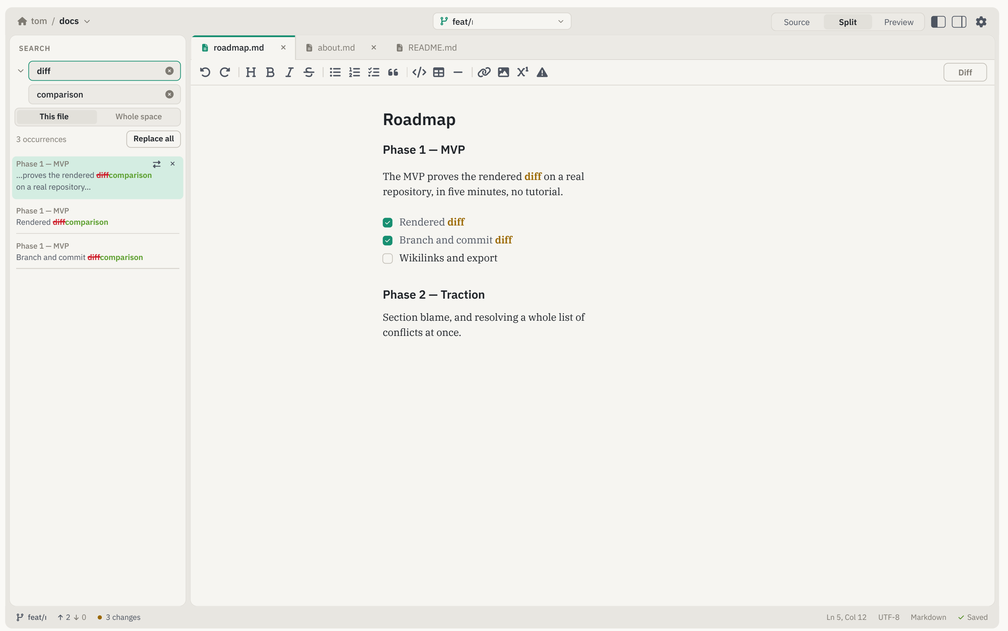

The one the pointer is on wears the pill and carries the actions. A pair of buttons on every row, times fifty, is a wall rather than a choice.

The count is what `Replace all` acts on

The line above the results says how many, and the control that changes them all sits beside it.

Searching · with replace

Searching with replace

Folded away by default

Most searching is reading, so replace waits behind a disclosure.

One, or all of them

Two buttons, because replacing the occurrence you are on and rewriting the file are different risks.
