Git · commit

Staging what changed and recording it, without leaving the window.

Committing

Committing

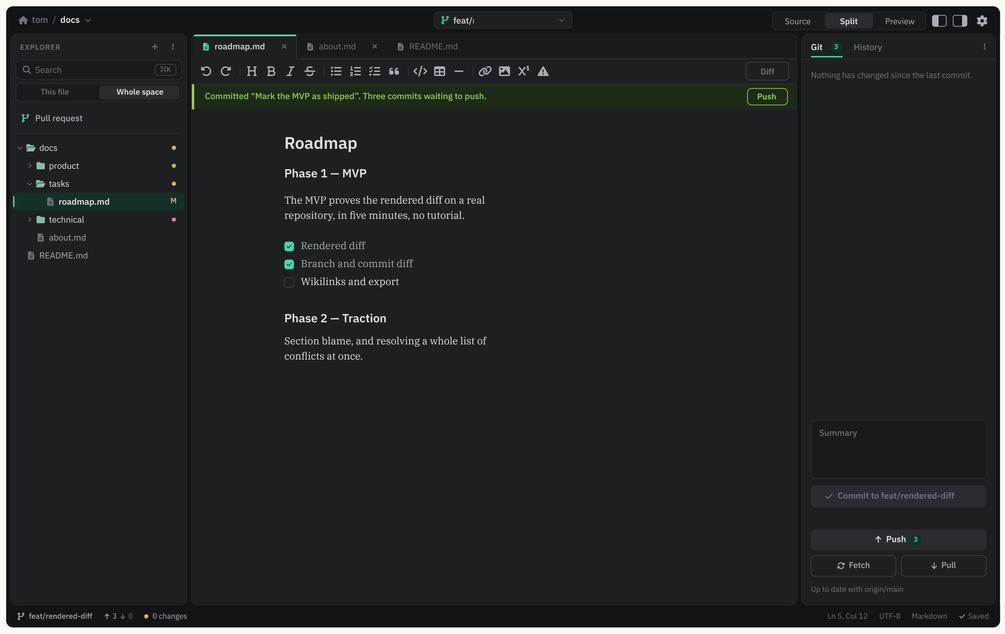

The list is the repository's
A commit records the index, so a file staged outside the space goes in whether or not it is drawn.

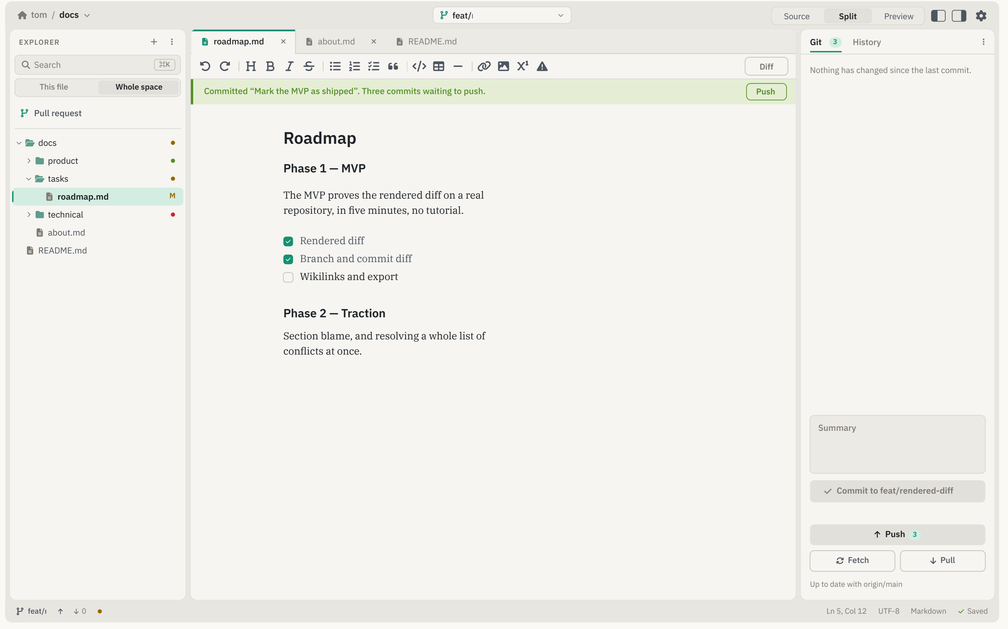

A letter as well as a colour
Each row says what happened twice, because colour is never the only signal.

Whole files only
Everything at once or one file at a time. There is no hunk-level staging.

A message is required
Committing with nothing staged is disabled rather than refused afterwards.

Commit succeeded

Commit succeeded

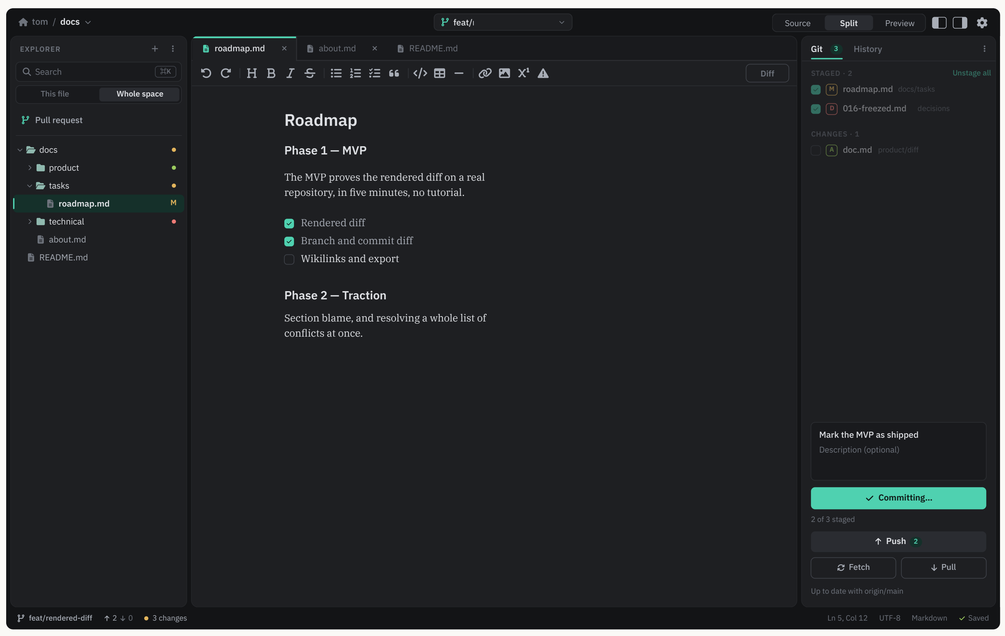

A commit that worked says so
An emptied list is not a confirmation — it looks exactly like a space where nothing had changed.

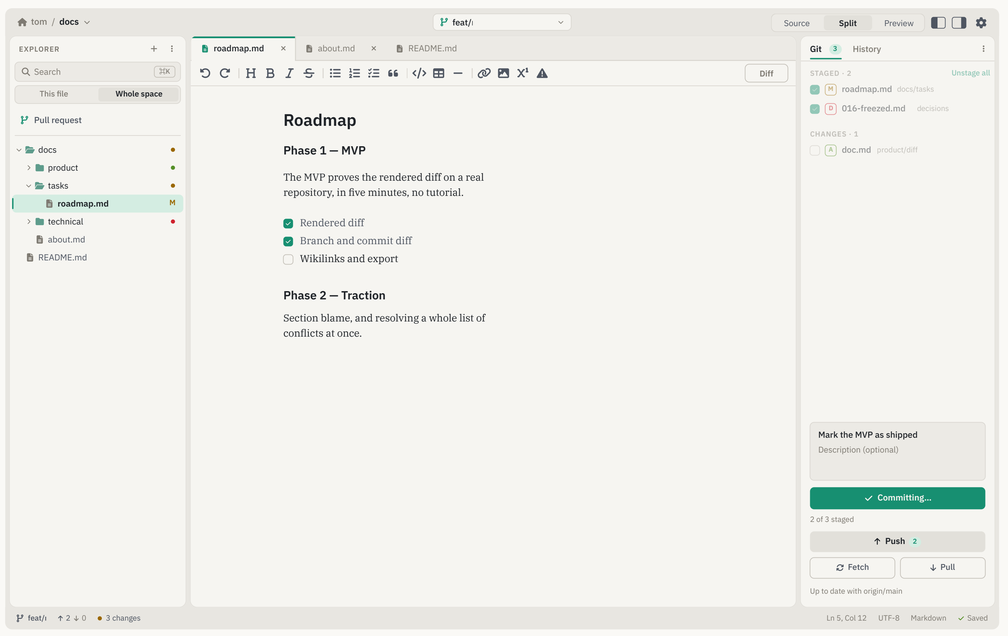

The band quotes the message, not the sha
The message is what somebody just wrote; the sha is what history is for.

It names no branch
The branch is already in the top bar and in the status bar. One fact, one wording per surface.

Push is its one action
The band says how many commits are now waiting, and carries the way to publish them.

Commit in progress

Commit in progress

The button carries the verb
While the commit runs it says so and shows a spinner. A control that only goes quiet leaves somebody wondering whether the click landed.

The rows it will change are dimmed
What the operation touches says so, which saves every other surface from having to.

Nothing else is taken away
The message box, the list and the remote controls stay where they are; only what is running changes.

One at a time
Git serialises them per space underneath, so a second press would only queue.
