Git · connection

What the right column says when the link to the remote is the problem — and why the button keeps its verb.

No network

No network

The line is the link, the band is the action

A band says what a press produced; this line says what the connection is. One appears after somebody asks, the other is true whether or not anybody asked.

It is not drawn when the link is healthy

A row that says everything is fine is a row nobody reads. The column stays quiet until it has something to say.

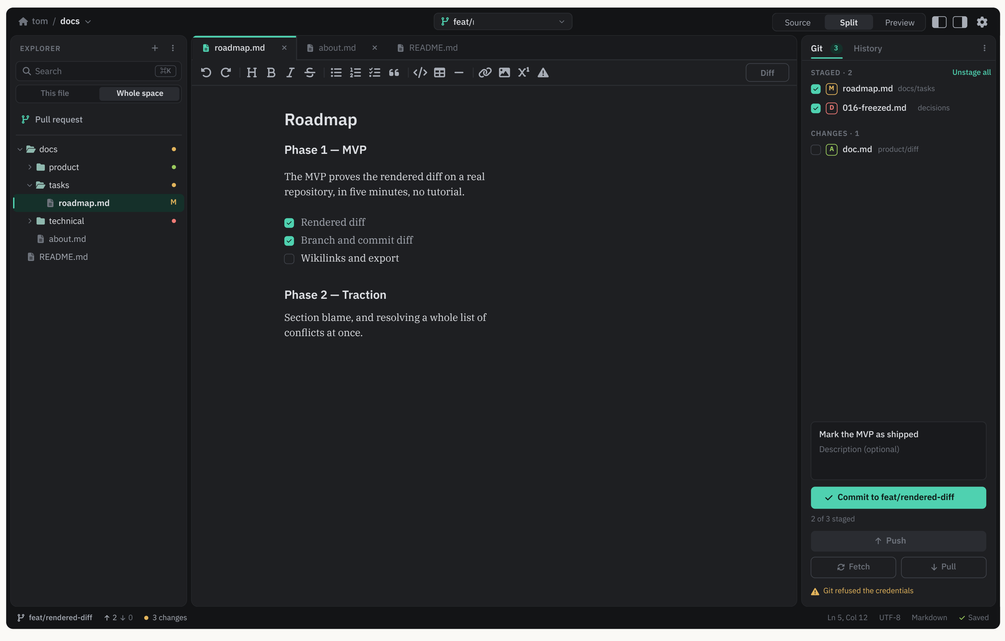

The three controls go unavailable, not away

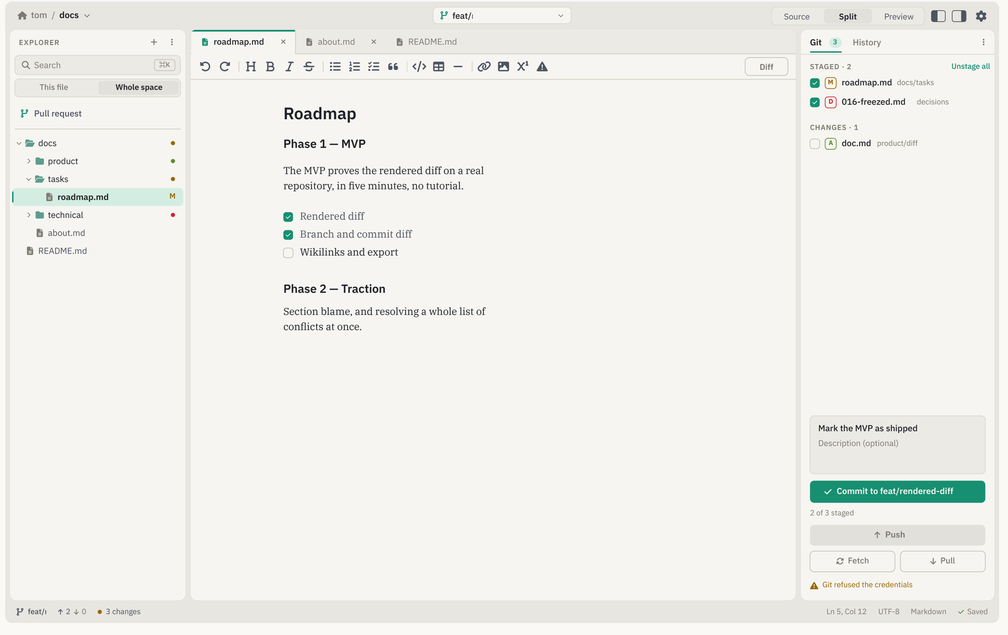

The network can come back, so the buttons stay where they are and say later rather than never.

Committing is untouched

Staging, writing a message and committing reach no remote. A space that cannot publish is still a space somebody is writing in.

Credentials refused

Credentials refused

Trying again answers the same

This is the one failure whose remedy is not Try again, so nothing here offers it — an action that cannot change the answer is a promise the app cannot keep.

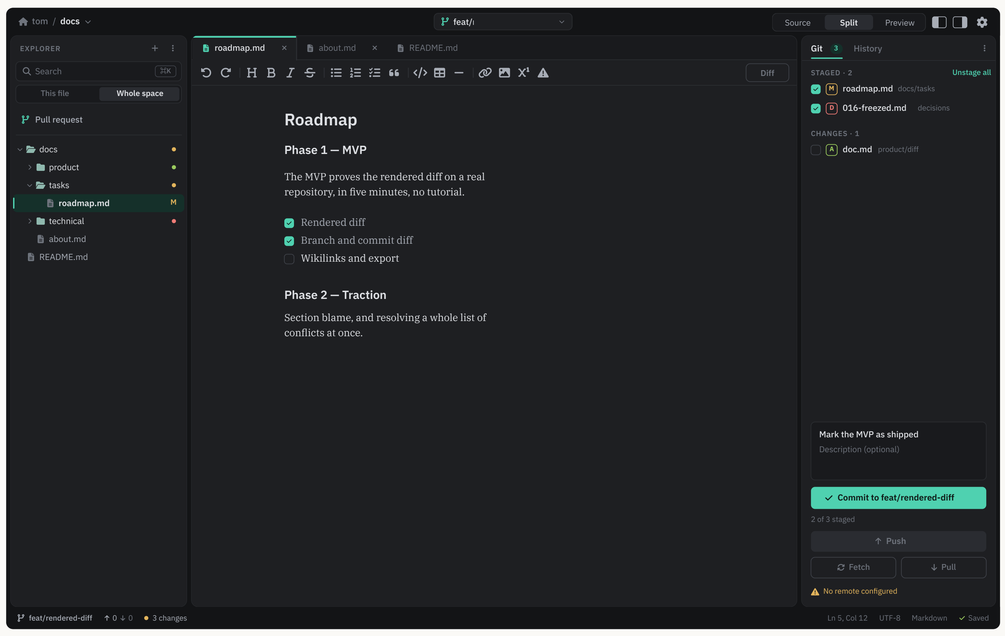

It says what was refused, never why

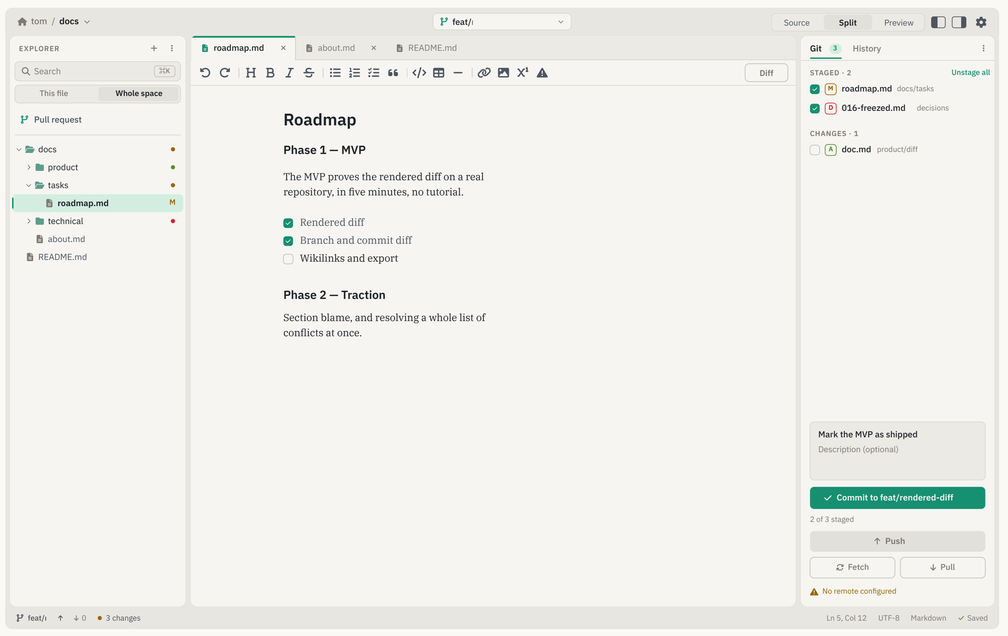

Git refused the credentials is honest; a guess about an expired token, a locked key or a wrong password would not be.

The work is not at risk

Nothing was published and nothing was lost. The commits are still here, and the column that writes the next one keeps working.

No remote

No remote

The controls stay, unavailable

A column whose foot changes shape with the weather is a column nobody can aim at. They say not now rather than disappearing.

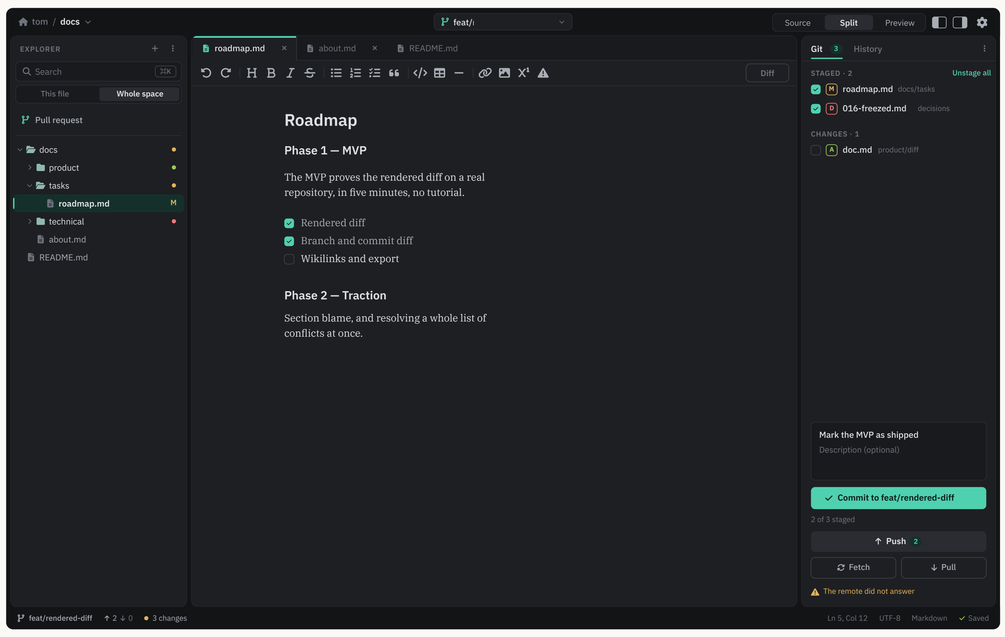

The count leaves, because it would lie

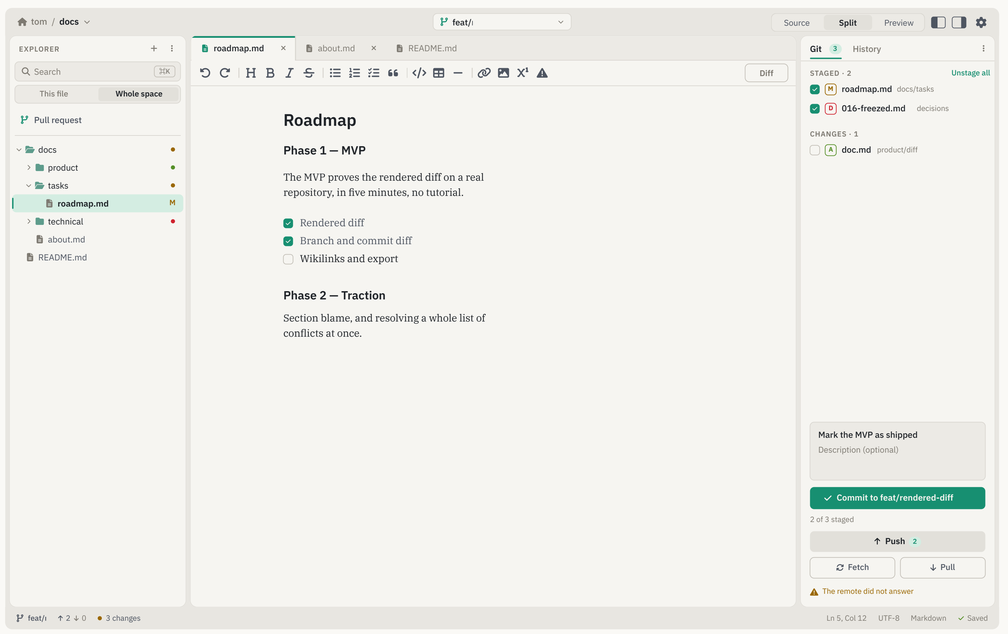

Ahead is counted against a remote. With none, the button reads Push with no number and the status bar drops the drift.

Committing is untouched

A repository without a remote is a repository: stage, describe, commit. Only publishing is missing.

Timed out

Timed out

The one that can answer differently

A remote that did not answer may answer next time, so the controls stay live — this is the failure where trying again is the remedy.

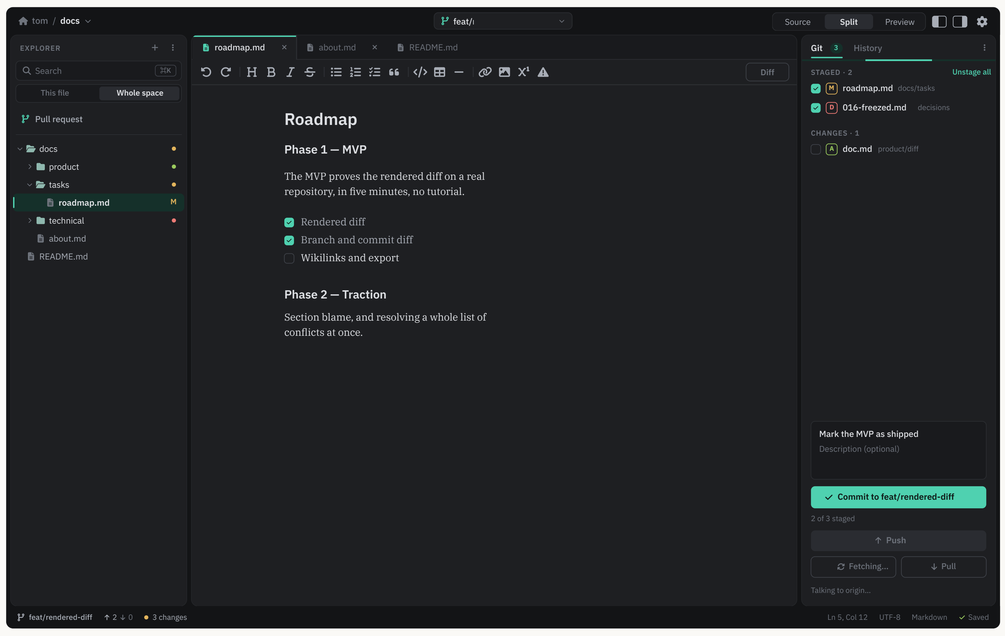

Silence is not a refusal

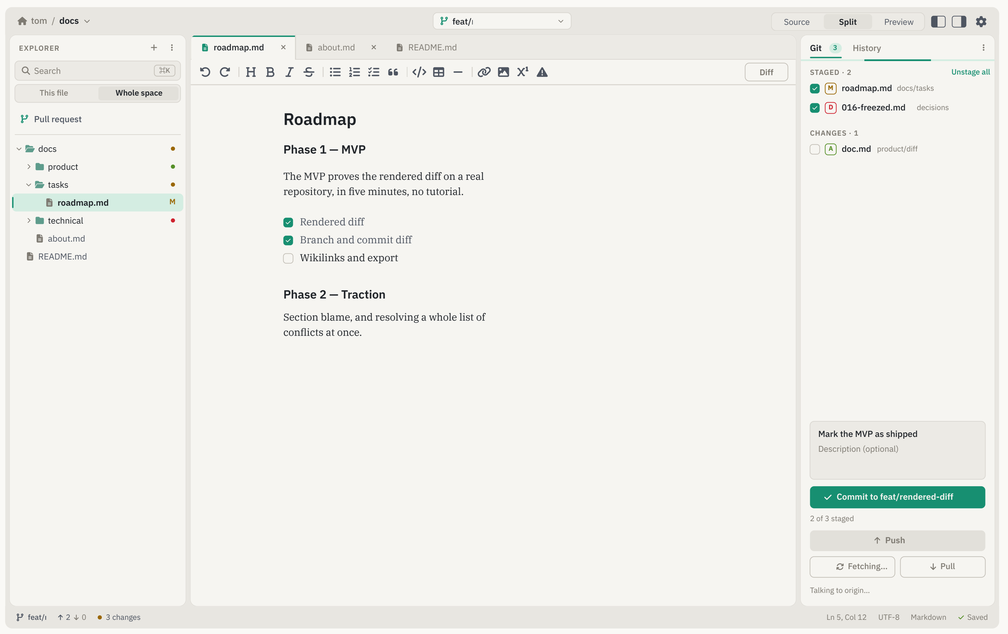

The remote did not answer says what happened. The remote is down would be a guess about a machine that may be fine.

Working is not a warning

The line wears modified here and accent while a request runs, and the glyph changes with it — the difference is never colour alone.

Talking to the remote

Talking to the remote

A bar across the top of the column

It spans the panel that owns every request, so the signal is the column's rather than one button's — and it says what is happening: data is coming from the web.

The three controls go unavailable

You already asked. A second press would queue a second request against a remote that is answering the first, so the buttons say wait rather than accept it.

The pressed one still names itself

Disabled does not mean silent: the button that started it reads Pushing…, so the bar never leaves a reader guessing which of the three is in flight.

Committing keeps working

The bar is for the network. Staging, writing a message and committing touch no remote, so nothing about them is taken away while it runs.
