Git

The Git workflow as a first-class citizen, without a terminal.

File history

File history

Scoped to this document
Only the commits that changed the open file, newest first.

Who, when, and what it was called
Plus the abbreviated sha, the only one of the four that names it elsewhere.

A version opens rendered
Not raw diff text, and never typed into. There is always a way back.

Reading a version

Reading a version

A past version is read, never typed into
While one is open the editor is not offered at all — the modes give way to the version's own bar.

Rendered, not raw diff text
Opening a history entry shows that version of the document the way a reader would see it.

The band names the commit and carries the way back
It sits where every other piece of news from git sits, so there is one place to look.

The list is this file's
Only the commits that changed the open document, most recent first — and with nothing open the panel says so rather than showing the repository's log.

Committing

File history
