Git · remote

Publishing, and what the remote answers when it will not take it.

Push rejected

Push rejected

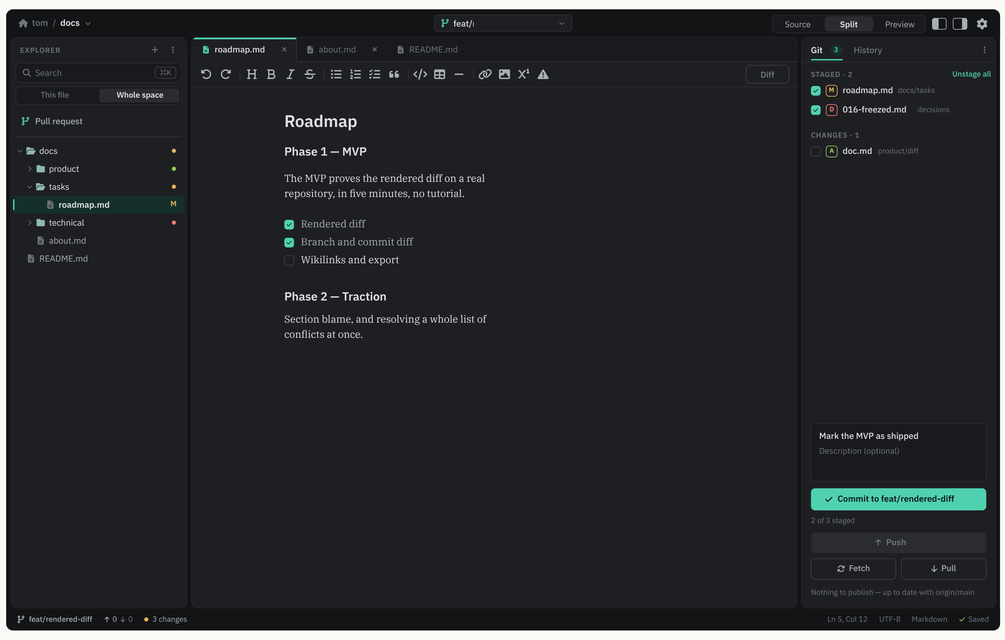

The banner is the column
The message box gives way to it rather than competing for the height.

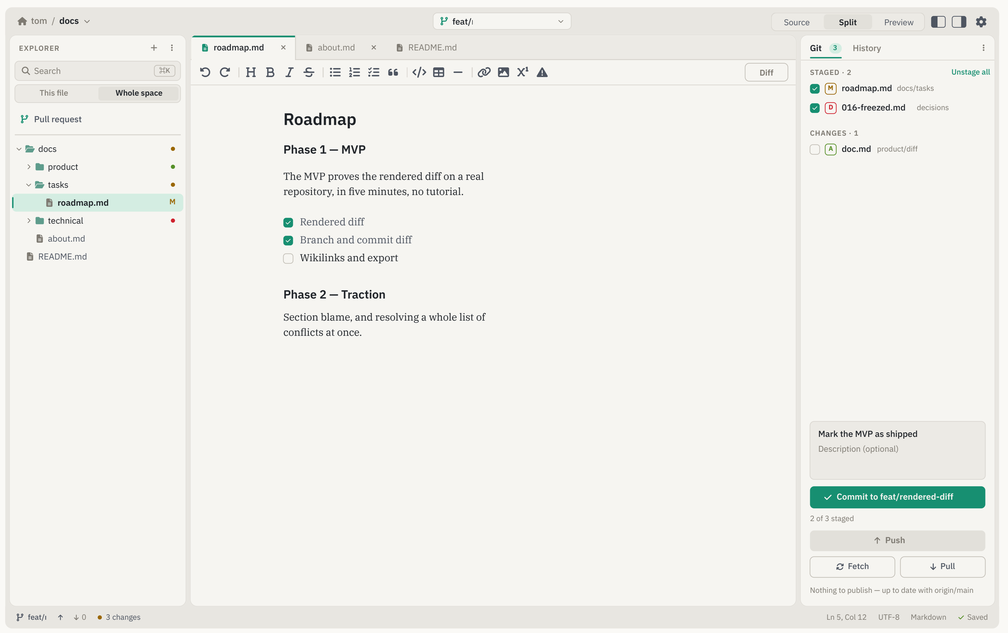

Pull is not a fourth button
It appears as the remedy inside the rejection, where it is needed.

Nothing you committed is lost
The wording says so, because that is the question somebody has at that moment.

Ahead and behind, or nothing
A zero beside a zero is chrome that has to be read to be ignored.

Nothing to push

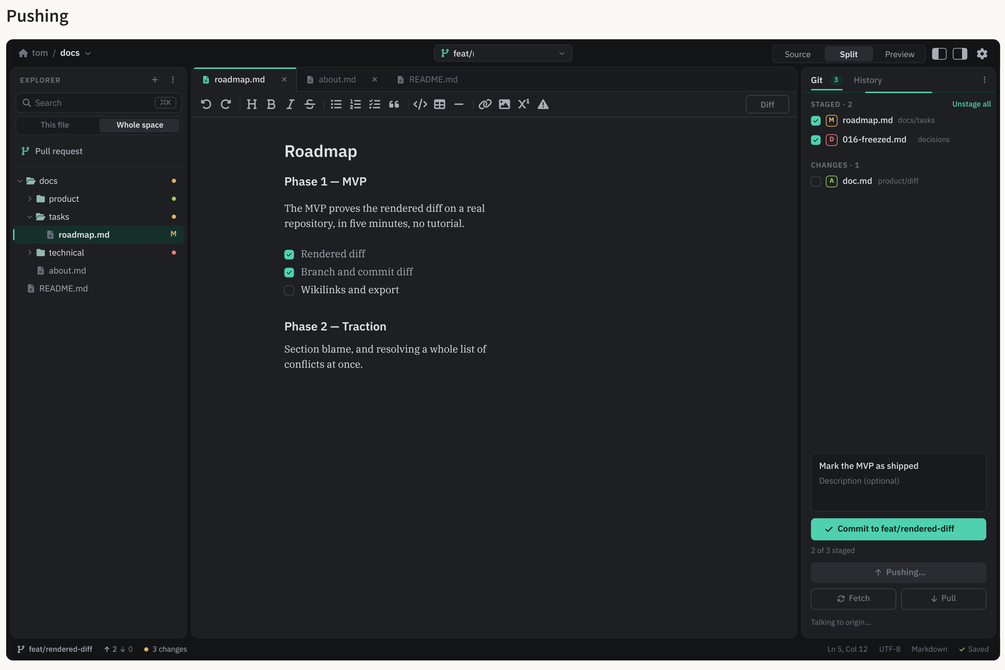

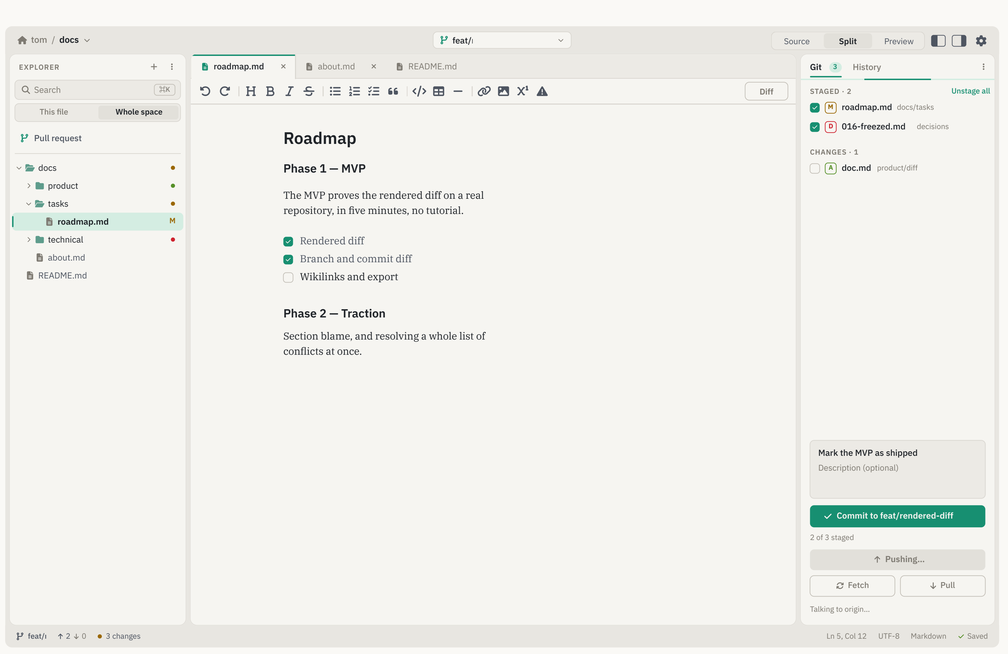

Nothing to push

The button says it
With nothing to publish, Push carries no number and is unavailable, rather than the attempt being refused afterwards.

The counter says nothing either
The status bar drops the item rather than drawing a zero beside it.

Pushing

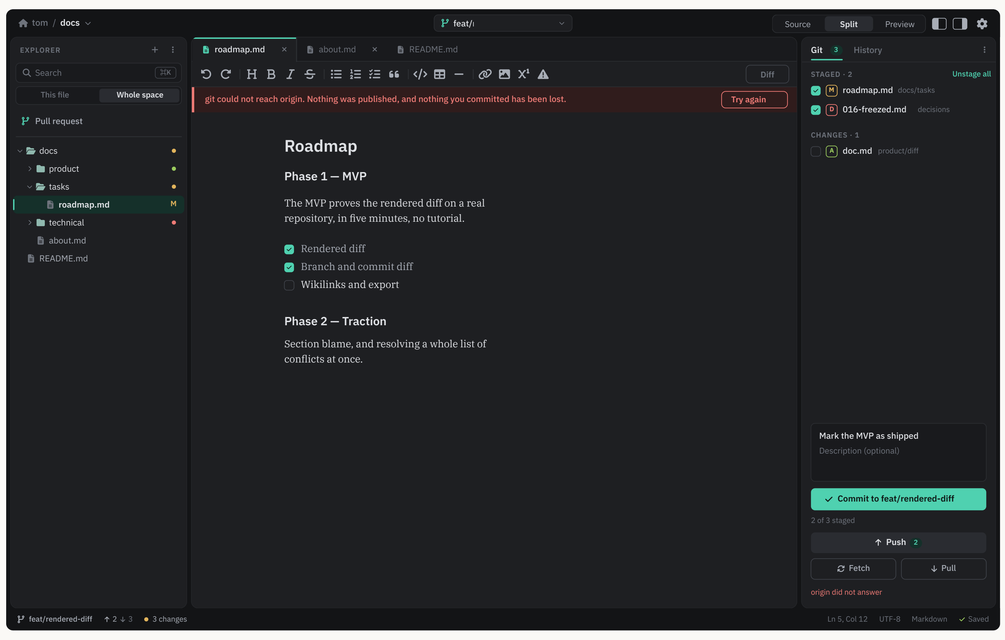

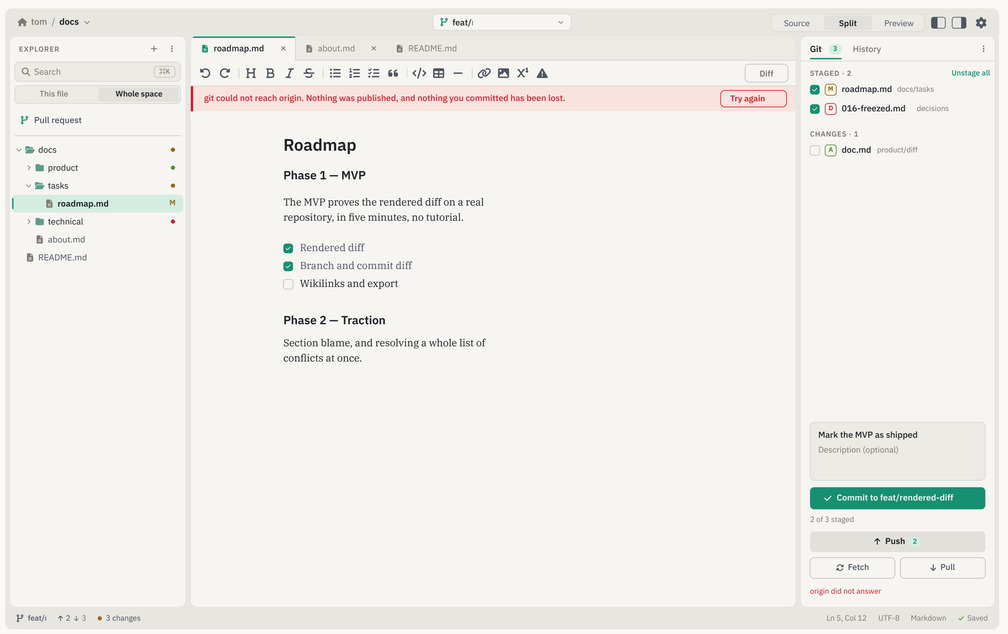

Pushing

One at a time
The working button names what it is doing and the others wait, because git serializes them per space underneath anyway.

The count leaves while it runs
The number is about to change, so the button drops it rather than showing a figure that is already stale.

Push failed

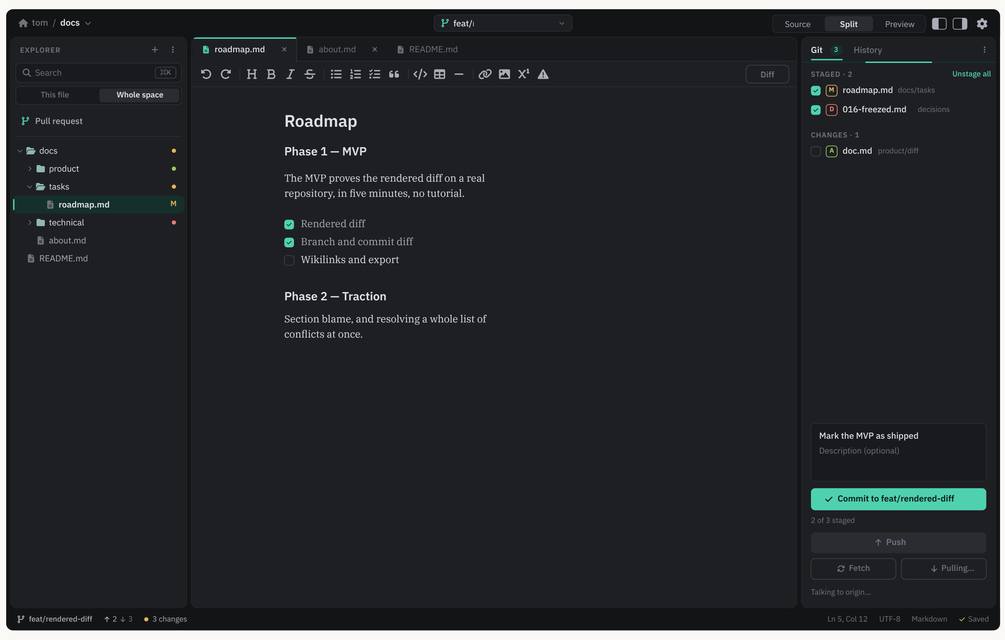

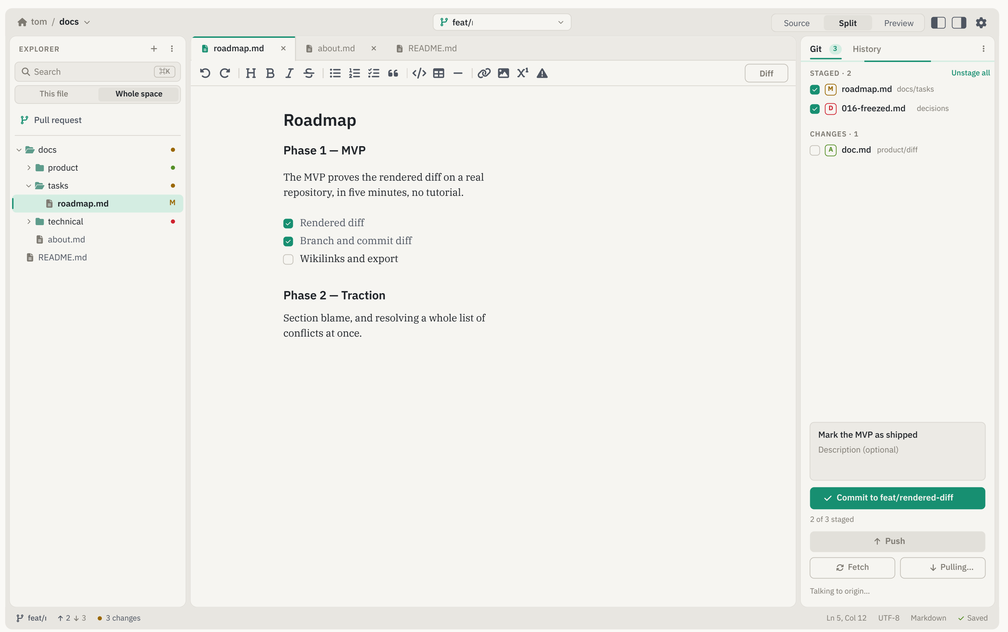

Push failed

A failure with no remedy is still said
A push that cannot reach the remote raises the band, says that nothing was published, and offers to try again.

The column keeps working
The news is a band above the document. The changes list, the message box and the history stay where they are.

Pulling

Pulling

A pull merges, and never rebases
The app decides this rather than inheriting whatever the machine happens to be configured with.

Only a pull writes to disk
Fetch alone never changes a file. After a pull the tree is walked again, because the app knows it wrote.

The one running says which
Only one remote action runs at a time, and the button that was pressed is the one that says so.

The count leaves while it runs
A number that is in the middle of being changed is not a number to read.

Pull conflicted

Pull conflicted

A stop in the middle is a state, not an error
The band says the pull stopped, how many documents conflict, and that nothing committed has been lost — a merge rewrites no commit.

The state belongs to the repository
It survives the window closing and reopening, so it is read from git rather than remembered from the action that caused it.

One action, and it is not resolving
The band offers `Abort the pull` and nothing else. Resolving is editing the document, which is its own subject.

Concluding the merge is a commit
Not a fourth button: the box arrives filled with the message git already wrote, editable like any other.
